Spring 2022 ECE 6913 Section A, Quiz 2 Solutions

Problem 1. This problem explores energy efficiency and its relationship with performance. The parts of this problem assume the following energy consumption for activity in Instruction memory, Registers, and Data memory. You can assume that the other components of the datapath consume a negligible amount of energy. ("Register Read" and "Register Write" refer to the register file only.)

I-Mem	1 Register Read	Register Write	D-Mem Read	D-Mem Write
140pJ	70pJ	60pJ	140рЈ	120pJ

Assume that components in the datapath have the following latencies. You can assume that the other components of the datapath have negligible latencies.

I-Mem	Control	Register Read or Write	ALU	D-Mem Read or Write
200 ps	150 ps	90 ps	90 ps	250 ps

1.1 How much energy is spent to execute an **addi** instruction in a single-cycle design and in the five-stage pipelined design

```
I-Mem is read, two registers are read, and a register is written
We have: 140pJ + 2*70pJ + 60j = 340pJ
```

1.2 How much energy is spent to execute a **lw** instruction in a single-cycle design

```
140pJ + 2*70pJ + 60pJ + 140pJ = 480pJ
```

1.3 How much energy is spent to execute a **beq** instruction in a single-cycle design

```
I-Mem + 2 registers = 140pJ + 2 * 70pJ = 280pJ
```

Problem 2.

One difference between a write-through cache and a write-back cache can be in the time it takes to write. During the first cycle, we detect whether a hit will occur, and during the second (assuming a hit) we actually write the data.

Let's assume that 50% of the blocks are dirty for a write-back cache. For this question, assume that the write buffer for the write through will never stall the CPU (no penalty). Assume a cache read hit takes 1 clock cycle, the cache miss penalty is 50 clock cycles, and a block write from the cache to main memory takes 50 clock cycles. Finally, assume the instruction cache miss rate is 0.5% and the data cache miss rate is 1%. Assuming that on average 26% and 9% of instructions in the workload are loads and stores, respectively, estimate the performance of a write-through cache with a two-cycle write versus a write-back cache with a two-cycle write.

```
CPU performance equation: CPUTime = IC * CPI * ClockTime
CPI = CPIexecution + StallCyclesPerInstruction
We know:
Instruction miss penalty is 50 cycles
Data read hit takes 1 cycle
Data write hit takes 2 cycles
Data miss penalty is 50 cycles for write through cache
Data miss penalty is 50 cycles or 100 cycles for write back cache
Miss rate is 1% for data cache (MRD) and 0.5% for instruction cache (MRI)
50% of cache blocks are dirty in the write back cache
26% of all instructions are loads
9% of all instructions are stores
Then: CPIexecution = 0.26 * 1 + 0.09 * 2 + 0.65 * 1 = 1.09
Write through
StallCyclesPerInstruction = MRI * 50 + MRD * (0.26 * 50 + 0.09 * 50) = 0.425
so: CPI = 1.09 + 0.425 = 1.515
                                           (1)
Write back
StallCyclesPerInstruction = MRI * 50 + MRD * (0.26 * (0.5 * 50 + 0.5 * 100) + 0.5 * 100)
0.09 * (0.5 * 50 + 0.5 * 100)) = 0.5125
so: CP I = 1.09 + 0.5125 = 1.6025
                                           (2)
Comparing 1 and 2 we notice that the system with the write back cache is 6%
slower.
```

Problem 3.

Consider the following RISC V Instruction sequence executing in a 5-stage pipeline:

```
or x13, x12, x11
ld x10, 0(x13)
ld x11, 8(x13)
add x12, x10, x11
subi x13, x12, 16
```

3.1 Identify all of the data hazards and their resolution with NOPs assuming no forwarding or hazard detection hardware is being used

Hazards identified:

NOPS introduced to resolve Hazards:

subi x13, x12, 16 Ex to 1^{st} only RAW Hazard resolved with 2 NOPs

3.2 If there is forwarding, for the first seven cycles during the execution of this code, *specify* which signals are asserted in each cycle by hazard detection and forwarding units in Figure below.

Mux control	Source	Explanation			
ForwardA = 00	ID/EX	The first ALU operand comes from the register file.			
ForwardA = 10	EX/MEM	MEM The first ALU operand is forwarded from the prior ALU result.			
ForwardA = 01 MEM/WB		The first ALU operand is forwarded from data memory or an earlier ALU result.			
ForwardB = 00	ID/EX	The second ALU operand comes from the register file.			
ForwardB = 10 EX/MEM		The second ALU operand is forwarded from the prior ALU result.			
ForwardB = 01 MEM/WB		The second ALU operand is forwarded from data memory or an earlier ALU result.			

	Clock Cycle	1	2	3	4	5	6	7	8	9	10
1	or	IF	ID	EX	MEM \	WB					
2	ld		IF	ID '	EX	MEM	WB				
3	ld			IF	ID	EX	MEM \	WB			
4	NOP	mandatory NOP for which no forwarding solution possible: load-data-use									
5	add					IF	ID	EX \	MEM	WB	
6	subi						IF	ID	EX	MEM	WB

(1)	A=x	B=x	(no instruction in EX stage yet)
(2)	A=x	B=x	(no instruction in EX stage yet)
(3)	A=0	B=0	(both operands of the or instruction: $x11$, $x12$ come from Reg File)
(4)	A=2	B=0	(base (RS1) in first 1d (x13) taken from EX/MEM of previous instruction)
(5)	A=1	B=0	(base (RS1) in 2nd 1d (x13) taken from MEM/WB of a previous instruction)
(6)	A=x	B=x	(no instruction in EX stage yet because NOP introduced to resolve MEM to 1^{st}
(7)	A=0	B=1	(RS2 in the add instruction is $\times 11$ which is forwarded from MEM/WB of 2^{nd}
			ld, the result of the I^{st} ld (x10) has already been written into Reg File in CC 6
			- so, no forwarding necessary for first operand)
(8)	A=1	B=0	(RS1 of subi instruction forwarded from EX/MEM of add instruction)

Problem 4.

. Consider the following program and cache behaviors.

Data Reads per	Data Writes per	Instruction	Data Cache Miss	Block Size
1K instructions	1K instructions	Cache Miss Rate	Rate	(Bytes)
300	150	0.5%	5%	128

Suppose a CPU with a write-through, write allocate cache achieves a CPI of 2.

4.1 What are the read and write bandwidths (measured by bytes per cycle) between RAM and the cache? (Assume each miss generates a request for one block.). For a write-allocate policy, a write miss also makes a read request to RAM – please be sure to consider its impact on Read Bandwidth

Instruction Bandwidth:

When the CPI is 2, there are, on average, 0.5 instruction accesses per cycle.

0.5 instructions read from Instruction memory per cycle

0.5% of these instruction accesses cause a cache *Read* miss (and subsequent memory request).

[0.5 instr/cycle] x [0.005 misses/instruction] = missed instructions/cycle

Assuming each miss requests one block and each block is 128 bytes [16 words with 8 bytes (64 bits) per word], instruction accesses generate an average of

[0.5 instr/cycle] x [0.005 misses/instruction] x[128 bytes/miss] =

= 0.32 bytes/cycle of read traffic

Read Data bandwidth:

30% of instructions generate a *read* request from data memory.

[0.5 instr/cycle] x [0.3 Read Data Accesses/instruction] = [0.15 Read Data Accesses / cycle] 5% of these generate a cache miss;

[0.15 Read Data Accesses / cycle] x [0.05 misses / Read Data Access] = 0.0075 Read Misses/cycle Assuming each miss requests one block and each block is 128 bytes [16 words with 8 bytes (64 bits) per word],

[0.0075 Read Misses/cycle] x [128 Bytes/block] x [1 block/miss] = 0.0075 x 128 Bytes/cycle = 0.96 Bytes/cycle

Write Data bandwidth:

15% of instructions generate a *write* request into data memory.

[0.5 instr/cycle] x [0.15 Write Data Accesses/instruction] = [0.075 Write Data Accesses / cycle] All of the words written to the cache must be written into Memory:

[0.075 Write Data Accesses / cycle] x [8 bytes/word] x [1 word/write-through] = 0.6 Bytes/cycle

For a Write-allocate policy, a Write miss also makes a read request to RAM

[0.5 inst/cycle] x [0.15 Write Data Accesses/instruction] x [0.05 misses/Write Data Access] x [128 Bytes/miss] = 0.48 Bytes/cycle

Assuming each miss requests one Word (8 bytes) since this is a write-through cache with only 1 word written per miss into memory,

[0.00375 Write Misses/cycle] x [8 Bytes/word] x [1 word/miss] = 0.03 Bytes/cycle

Total Read Bandwidth

0.32 (Instruction memory) + 0.96 (data memory) + 0.48 (Write-miss in Write-through cache with Write Allocate) Bytes/cyle = 1.76 Bytes/cycle

<u>Total Write Bandwidth:</u>
